Ordinary Differential Equations

Introduction

6 Abstract of every vibration/flow is asmooth curve / diffeqn.

- A carve can be represented as a function
- In $y = f(x), x$ is independent variable &y is a dependent variable

  also in $z = f(x, y), x, y$ are independent variables &
  z is dependent variable.

Differential equation

An equation involving derivative(s) of dependent variable with respect to independent variable(s) is called differential equation.

$$\text{e.g: } x \times \frac{dy}{dx} + y = 0$$

ODE

A diffeq. involving depen derivortives of dependent variable with respect to only one independent variable

`is`

- only polyromial diff. gqs have degree

$$3\left(\frac{d^2y}{dx^2}\right)^4 + \left(\frac{dy}{dx}\right)^5 = 0$$

  degree 4

- Order: Order of highest order derivutive of dependent variable, wrt. independent variable involved in the equation.
- Degree: If diffeqn. is a polynomial equation of derivative, the highest (power (positive integral index) of highest order derivative is its degree.

  creneral form: $f(x, y, y') = 0$

$$\text{or } y' = g(x, y)$$
$$\text{cy: } y^2 = \sqrt{x^2 + y^2}$$

1^{st} Order LDE

$$y' + P(x)y = Q(x)$$

: p, q are continuous in same interval I
solution: $g(F) = \int Q \cdot (F)dx + C$. $F = e^{\int Pdx}$ Integration factor

$$1.\ y_1' + 2xy = x$$

A). Given is an 1^{st} order LDE

$$P = 2x, Q = \infty,$$
$$\therefore F = e^2 \int x \cdot dx = e^{x^2} \text{ (integrating factor}$$
$$\therefore \text{ Solution: } y \cdot e^{x^2} = \int x \cdot e^{x^2} dx + c \quad x^2 =$$
$$= \tfrac{1}{2} e^{x^2} + c \quad 2xdx =$$
$$\therefore y = \tfrac{1}{2} + e^{-x^2} \cdot c \quad x \cdot dx$$

2. Solve $\frac{dy}{dx} + 2y\tan(x) = \sin(x)$

$$\begin{aligned} P(x) &= 2\tan(x), Q(x) = \sin(x) \\ IF &= e^{\int P \cdot dx} \\ &= e^{2 \cdot \ln|\sec(x)|} \\ &= |\sec(x)|^2 \equiv \sec^2(x) \end{aligned}$$

Solution $= y \cdot \sec^2(x) = \int \sin(x) \cdot \sec^2(x) dx + c$

$$= \int \cdot \sec(x)\tan(x)dx + c$$
$$= \sec(x) + c$$

$$y = \cos(x) + \cos^{\circ 2}(x) \cdot c$$

3. Find solution of initial value problem:

$$x^2 y' - xy = x^4 \cdot \cos(2x), y(\pi) = 2\pi$$

A $\quad x^2 y' - xy = x^4 \cdot \cos(2x)$
$\therefore y'_{-} - x^{-1} y = x^2 \cdot \cos(2x)$
$\therefore P(x) = -x^{-1}, Q(x) = x^2 \cdot \cos(2x)$
$\therefore IF = e^{\int p(x) \cdot dx} = e^{-\int x^{-1} \cdot dx} = e^{-10[x]} = 0\left(x^2\right)^{-1}$
$\therefore$ Solution: $y \cdot IF = \int Q \cdot IF \cdot dx + C$

$$
\begin{aligned}
y \cdot (x)^{-1} &= \int x^2 \cdot (x)^{-1} \cdot \cos(2x) \cdot dx + c \\
&= \int x \cdot \cos(2x) dx + c \\
&= \frac{xx \cdot \sin(x)}{2} - \frac{1}{2} \int \sin(2x) dx + c \\
&= \frac{x \sin(2x)}{2} + \frac{\cos(2x)}{4} + c \\
\therefore y &= \frac{x^2 \cdot \sin(2x)}{2} + \frac{x \cdot \cos(2x)}{4} + x^4 \cdot c
\end{aligned}
$$

I is given that $y(\pi) = 2\pi$

$$\therefore 2\pi = \frac{\pi^2 \cdot \sin(2\pi)}{2} + \frac{\pi \cdot \cos(2\pi)}{4} + \pi \cdot c$$

$$\therefore 2 = \frac{1}{4} + c \Rightarrow c = 1\frac{3}{4} = \frac{7}{4}$$

Substitute in (2) to get specific solutions

$$y = \frac{x^2 \sin(2x)}{2} + \frac{x \cdot \cos(2x)}{4} + \frac{7}{4}x$$

4 Solve $y' - 2xy = 2$

5. Solve $xy' - 2y = -x$

$G =$

$4y' - 2xy = 2x$

Let $P(x) = -2x, Q(x) = 2x$

$IF = e^{\int F dx} = e^{\int -2x \cdot dx} = e^{-x^2}$

$\therefore$ solution: $y \cdot e^{-x^2} = \int 2x \cdot e^{-x^2} dx + c$

$e^{\int p} = e^{F+c} = e^F \cdot e^c$

~~both~~ e^c exists in both sides $\therefore$

$y \cdot e^F \cdot e^c = e^c \int \dots + c$

$\rightarrow y \cdot e^F = \int \dots + \frac{c}{e^c}$ is another const

$$\text{let } -x^2 = t, \Rightarrow -2x \cdot dx = dt$$
$$\text{Put } -x^2 = t$$
$$\therefore \int \Big(2x \cdot e^{-x^2} dx + c = -\int e^t dt = \frac{-e^t + 0}{}$$
$$= -e^{x^2} +$$
$$-2xdx = dA$$
$$\therefore y = 1 + e^{x^2} \cdot c$$
$$\int 2xe^{-x^2} dx = -\int e^t dt$$
$$5.\ xy' - 2y = -x$$
$$= -e^t$$
$$= -e^{-n^2}$$
$$\therefore y' - 2x^{-1} \cdot y = -$$
$$\therefore P(x) = -\frac{2}{x}, Q(x) = -$$
$$\therefore IF = e^{\int A1x} = e^{-2\int 1/x \cdot dx} = e^{-2\ln(x)} = x^{-2}$$
$$y \cdot x^{-2} = \int x^{-2} \cdot -1 + c$$
$$= \frac{2^{-1}}{-1} \text{ ar- } + c = \frac{1}{x} + c$$

$$\therefore y = x + cx^2.$$

6. $xy' + 2y = \frac{\cos(x)}{x}$

$y' + \frac{2}{x} \cdot y = \frac{\cos(x)}{x^2}$
$P(x) = \frac{2}{x}, Q(x) = \frac{\cos(x)}{x^2}, IF = e^{\int p \cdot dx} = e^{\ln\left(x^2\right)} = x^2 \ y \cdot IF = \int IF \cdot Q \cdot dx + c$
$y \cdot x^2 = \int x^2 \cdot \frac{\cos(x)}{x^2} \cdot dx + c = \int \cos(x) dx + c$
$y \cdot x^2 = \sin(x) + c \Rightarrow y = \frac{\sin(x)}{x^2} + \frac{c}{x^2}$

7. $y' + \frac{2y}{x} = \frac{4}{x}$,

$P(x) = \frac{2}{x}, Q(x) = \frac{4}{x}, \quad \text{F} = e^{\int Pdx} = e^{2 \cdot \int 1/x \cdot dx} = x^2$
$\therefore$ solution: $y \cdot x^2 = \int x^2 \cdot \frac{4}{x} dx + c = 2x^2 + c$
$\cdots y = 2 + \frac{c}{x^2}$
Given $y(1) = 6$,

$$\therefore \quad 6 = 2 + \frac{c}{1} \Rightarrow c = 4$$

$\therefore y = 2 + \frac{4}{x^2}$
Hw

1) $(x+1)y' + 2y = (x+1)^{5/2}$ 2) $xy' - 2y = x^4 e^x$
3) $xy' - y = 2x\ln(x)$ 4) $y' + y \cdot \tan(x) = \cos^2(x)$
5) $y' + y \cdot \cot(x) = \csc^2(x)$ 6) $xy' + y = (1+x)e^x$
7) $y' + 2xy = xe^{-x^2}$ 8) $xy' - 2y = x^3 e^x, y(1) = 0$

Variable Separable Equation

A differential equation of the form ' $m(x,y)dx+n(x,y)dy=0$ ' is a variable separable equation if it can be expressed in the form: $f(x)dx+g(y)dy=0$

Solve : $\frac{dy}{dx}=\frac{y}{x}$

$dy \cdot x = dx \cdot y \rightarrow \frac{dx}{x}=\frac{dy}{y}$

$\ln(35)+c=\ln(x0)+D \therefore \ln(y)=\ln \operatorname{lse}+c+D$

$x_y = x \times e^{c+p} \ldots 3x\sin(y)\cdot dx+(x^2+1)\cdot\cos(y)\cdot dy=0$

A) Divide by $\sin(y)\cdot(x^2+1)$

$$\therefore \frac{x}{x^2+1}dx+\frac{\cos(y)}{\sin(y)}dy=0$$
$$\frac{1}{2}\int\frac{2x\cdot dx}{x^2+1}+\int\frac{\cos(y)}{\sin(y)}dy=\ln(c)$$

let $t=x^2+1, dx2x=dt$, let $u=\sin(y), \frac{du}{dy}=\cos(y), dy\cdot\cos(y)=du$

$\therefore \frac{1}{2}\int\frac{dt}{t}+\quad-\int\frac{du}{u}=\ln(c)$

$=\frac{1}{2}\ln\left(x^2+1\right)+\ln(\sin(y))=\ln(c)$

$$\ln\left[\frac{\left(x^2+1\right)^2\sin(y)}{c}\right]=0\rightarrow\sin(y)=\frac{c}{\left(x^2+1\right)^2},$$
$$y=\sin^{-1}\left[\frac{c}{\left(x^2+1\right)^2}\right]$$

4. $\tan(\theta)dr+2r\cdot d\theta=0$

$$\frac{dr}{2r}+\frac{d\theta}{\tan(\theta)}=0$$
$$\int\frac{dr}{2r}+\int\underbrace{\int\frac{d\theta}{\tan(\theta)}}_{\operatorname{tat}(\theta)d\theta}=\ln(c)$$
$$=\frac{1}{2}\ln(\gamma)+\ln(\sin(\theta))=\ln(c)$$
$$=\ln(\sqrt{x})+\ln(\sin(\theta))=\ln(c)$$
$$\ln(\sqrt{r})=\ln\left[\frac{c}{\sin(\theta)}\right]$$
$$\sqrt{\gamma}=\sec\frac{c}{\sin(\theta)}\longrightarrow r\cdot\gamma\cdot\sin^2(\theta)=c$$

$4xydx+\left(x^2+1\right)dy=0$

$\rightarrow\frac{4x}{x^2+1}dx+\frac{dy}{y}=0$

2. $\int\frac{2x}{x^2+1}dx+\int\frac{dy}{y}=\overset{\ln(c)}{\cancel{0}} = 2\ln(x^2+1)+\ln(y)=\ln(c)$

$\rightarrow y=\frac{c}{(x^2+1)^2}$

Homogenfous Differential Equation

An differential equation that can be reduced into the form: $\frac{dy}{dx} = F\left(\frac{y}{x}\right)$ is called homogerious differential equation This can be solved by putting $y = vx$ and hence reducing to variable separable form.

1. Solve $2xy \cdot \frac{dy}{dx} - y^2 + x^2 = 0$

$$2xy\frac{dy}{dx} = y^2 - x^2 \Rightarrow \frac{dy}{dx} = \frac{y^2 - x^2}{2xy} - (1)$$

pat $y = vx$ $v = \frac{y}{x}$

$$\begin{aligned}
&\therefore (1) \equiv v + x \cdot \frac{dv}{dx} = \frac{v^2x^2 - x^2}{2x^2v} = \frac{(v^2-1)}{2v} = \frac{(y^2/x^2 - 1)}{2 \cdot x/xx} \\
&x \cdot \frac{dv}{dx} = \frac{v^2 - 1}{2v} - v = \frac{v^2 - 1 - 2v^2}{2v} \\
&x \cdot \frac{dv}{dx} = \frac{-\left(1 + v^2\right)}{yv} \\
&\frac{2v}{(c1 + v^2)} \cdot dv = \frac{dx}{x} \\
&\therefore -\int \frac{2v}{(1+v^2)} dv = \int \frac{dx}{x} + \ln(c) \\
&= -\ln\left(v^2 + 1\right) = \ln(x) + \ln(c) \\
&x \equiv \ln\left(v^2 + 1\right) = -\ln(x) + \ln(c) \\
&\therefore v^2 + 1 = \frac{c}{x} \\
&\frac{y^2}{x^2} + 1 = \frac{c}{x} \Rightarrow y^2 + x^2 = cx
\end{aligned}$$

let $y = vx, \quad \therefore v = \frac{y}{x}$

$$\therefore \frac{dy}{dx} = 1 + \frac{vx}{x} = 1 + v$$

$= v + x \cdot \frac{dv}{dx} = 1 + v \Rightarrow x \cdot \frac{dv}{dx} = 1 \Rightarrow \frac{dx}{x} = dv$

$$\therefore \int \frac{dx}{x} = \int dv + c$$

$$= \ln(x) = v + c$$

$$y = \ln\left(\frac{x}{D}\right) \cdot x$$

Bernoülli's Differential Equation

A differential equation of form $y' + p(x)y = Q(x)y^n.n \in \mathbb{R}/\{0,1\}$ called Bernocilli's Differential equation

Method to solve:

i.) Divide by y^n

$$y^{-n} \cdot y' + p(x)y^{1-n} = Q(x) - (1)$$

2. put $z \leq y^{1-n}, \therefore \frac{dz}{dx} = (1-n)y^{-n} \cdot \frac{dy}{dx} \Rightarrow \underbrace{y^{-n} \cdot \frac{dy}{dx} = \frac{1}{1-n} \cdot \frac{dz}{dx}}_{(2)}$

3. Substitute (2) in (1):

$(1) \rightarrow \frac{1}{1-n} \cdot \frac{dz}{dx} + P(x) \cdot z = Q(x)$

$$\Rightarrow z' + (1-n)P(x) \cdot z = (1-n)Q(x)$$

This is FLDE. in dependent variable z
$\therefore$ Solution:

$$Z \cdot (I \cdot F) = \int (1-n)Q(x) \cdot IF \cdot dx + C \quad , IF = e^{\int (1-n) \cdot P(x) \cdot dx}$$

Solve following:
a) $y' + 2y = y^2$
A. Divide by y^2 :

$$y^{-2} \cdot y' + 2y^{-1} = 1$$

put $z = y^{-1} \quad \therefore z\frac{dz}{dx} = -y^{-2} \cdot \frac{dy}{dx}$
$\therefore$ (1) becomes:
$-\frac{dz}{dx} + 2z = 1 \Rightarrow \frac{dz}{dx} - 2x = -1$
This is FLDE.
$\therefore P(x) = -2, \quad Q(x) = -1$
$IF = e^{\int P dx} = e^{\int -2 \cdot dx} = e^{-2x}$
$\therefore$ General Solution:

$$\therefore z \cdot e^{-2x} = \int -e^{-2x} dz + c/2$$

$$zxe^{-2x} = \frac{1}{2}e^{-2x} + \frac{c}{2}$$

$$\text{now } z = y^{-1}$$

$$\therefore \quad y^{-1} \cdot e^{-2x} = \frac{1}{2}e^{-2x} + \frac{c}{2}$$

$$\therefore y = \frac{2}{1 + e^{2x} \cdot c}$$

Divide by y^4 :

$$y^{-4} \cdot \frac{dy}{dx} - y^{-3} \cdot \tan(x) = \sec(x) - (1)$$

let $z = y^{-3}, \quad \frac{dz}{dx} = -3.y^{-4} \cdot \frac{dy}{dx}$
multiply θ by -3 & substitute $\frac{dz}{dx}$

$$+3, \quad z\tan(x) = -3\sec(x)$$

$$\frac{dz}{dx}$$
$$P(x) = 3\tan(x) \quad Q(x) = -3\sec(x)$$
$$I:F = e^{\int P\cdot dx} = e^{3\int \tan x \cdot dx} = e^{\ln\left(\sec^3(x)\right)} = \sec^3(x)$$

multiply (2) by I.F.
$\sec^3(x) \cdot \frac{dz}{dx} + 3 \cdot \tan(x) \cdot \sec^3(x) z = -3\sec^4(x)$
Apply reverse product rule: $uv' + vu' = (4v)'$

$$\Rightarrow \frac{d}{dx}\left(\sec^3(x) \cdot z\right) = -3\sec^4(x)$$

$\int sc.^4 \to \int \mathrm{se}^2 \cdot \mathrm{sc}^2$
Integrate both sides: $\to (1+t^2)\, sc^2$

$$\sec^3(x) \cdot z = -3\int \sec^4(x) \cdot dx + c \tag{x}$$

$= \int (1+\infty) dt$

$$= -3\left[\tan(x) + \frac{\tan^3(x)}{3}\right] + c$$

$\Rightarrow \frac{\sec^3(x)}{y^3} = -3\tan(x) = \tan^3(x) + c$
$\therefore y = \frac{1}{\mathrm{sos}^5(x) \cdot \sqrt[3]{-3\tan(x) - \tan^3(x) + c}}$
d) $\frac{dy}{dx} + \tan(x)\tan(y) = \cos(x) \cdot \sec(y)$
A) This is B.D.E.
Divide by $\sec(y)$
$\cos(y)\frac{dy}{dx} + \tan(x)\sin(y) = \cos(x) \quad -(1)$
let $z = \sin(y)$. $\quad \frac{dz}{dx} = \cos(y) \cdot \frac{dy}{dx}$.
Substitute this in (1)
$\frac{dz}{dx} + \tan(x) \cdot z = \cos(x)$
let IF $= e^{\int \tan(x) \cdot dx} = e^{\ln(\sec(z))} = \sec(x)$
multiply both sides by T.F.
$\sec(x) \cdot \frac{dz}{dx} + \tan(x) \cdot \sec(x) \cdot z \cdot = 1$
$\equiv \frac{d}{dx}(\sec(x) \cdot z) = 1 \quad \Rightarrow \quad \sec(x) \cdot z = x + c \Rightarrow \sec(x) \cdot \sin(y) = x + c.$
$\therefore y = \sin^{-1}(\cos(x) \cdot (x+c))$
d) $\frac{dy}{dx} + x \cdot \sin(2y) = x^3 \cdot \cos^2(y)$
Divide by $\cos^2(y)$:
$\sec^2(y) \cdot \frac{dy}{dx} + \frac{x \cdot 2\sin(y)\cos(y)}{\cos^2(y)} = x^3$
$\sec^2(y)\frac{dy}{dx} + 2x \cdot \tan(y) = x^3 \quad -10$
let $z = \tan(y) \quad \frac{dy}{dx} = \sec^2(y) \cdot \frac{dy}{dx}$
substitute this in (1):
$\frac{dz}{dx} + 2x \cdot z = x^3$
let I.F $e^{\sqrt{2x} \cdot dx} = e^{x^2}$, demultiply both sides by I.F $e^{x^2} \cdot \frac{dz}{dx} + z \cdot 2x \cdot e^{x^2} = x^3 e^{x^2}$
$\Rightarrow \frac{d}{dx}\left(e^{x^2} \cdot z\right) = x^3 \varepsilon e^{x^2}$

$e^{x^2} z = \int x^3 \cdot e^{x^2} dx + c \longrightarrow$ let $t = x^2$, $dt = 2x \cdot dx$

$\downarrow$

$\frac{1}{2}\int t \cdot e^{t}$

$= \frac{1}{2} e^{x^2}(x^2 - 1) + c$

$= \tan(y) \cdot e^{x^2} = \frac{1}{2} e^{x^2}(x^2 - 1) + c$

$= \frac{1}{2}\left(t \cdot \int e^t dt - \int \int e^t dt \cdot dt\right)$

$= \frac{1}{2}(t \cdot e^t - e^t) = \frac{1}{2} e^t (t - 1)$

$y = \tan^{-1}\left(\frac{1}{2}(x^2 - 1) + e^{-x^2} \cdot c\right)$

1.) $\frac{dy}{dx} + y = xy^3$ **2)** $\frac{dy}{dx} - y\tan(x) = y^2 \cdot \sec(x)$

3) $\frac{dy}{dx} + \frac{y}{x} = \frac{y^2}{x}\ln(x)$

4) $\frac{dy}{dx} + xy = x^3 y^3$

Partial Differentiation

If $z = f(x, y)$ it can be differentiated partially wort x ory $\frac{\partial z}{\partial x} = \lim_{\Delta x \to 0} \frac{f(x+\Delta x, y) - f(x,y)}{\Delta x}$, Here we treat y as constant $z_x = \frac{\partial z}{\partial x}$

e.y: $z(x, y) = x^2 + y^2 + 2xy$,

$z_y = \frac{\partial z}{\partial x}\ \frac{\partial z}{\partial x} = 2x + 0 + 2y \quad 0$

or wirt. y by: $\frac{\partial z}{\partial y} = \lim_{\Delta y \to 0} \frac{f(x, y+\Delta y) - f(x,y)}{\Delta y}$ [we treat x constaint] $\frac{\partial z}{\partial y} = 0 + 2y + 2x$

find $\frac{\partial f}{\partial x}$&$\frac{\partial f}{\partial y}$ in following:

a) $f(x, y) = x^3 + 3x^2 y + xy^3$

A) $\frac{\partial f}{\partial x} = 3x^2 + 6xy + y^3 \quad , \frac{\partial f}{\partial y} = 0 + 3x^2 + 3xy^2$

b) $f(x, y) = 2x\cos(y) + 3x^2 y$

A) $\frac{\partial f}{\partial x} = 2\cos(y) + 6xy \quad \frac{\partial f}{\partial y} = -2x\sin(y) + 3x^2$

c)
$$f(x, y) = x\tan^{-1}\left(\frac{y}{x}\right)$$
$$f_x = \frac{1}{1 + y^2/x^2} \cdot \frac{\partial}{\partial x} \cdot \left(\frac{y}{x}\right) = \frac{y}{x^2} \cdot \frac{x^2}{x^2 + y^2} \cdot -\frac{1}{x^2} = \frac{-y}{x^2 + y^2}$$

$\Delta f_y = \frac{1}{1+y^2/x^2} \cdot \frac{\partial}{\partial y}\left(\frac{y}{x}\right) = \frac{x^2}{x^2+y^2} \cdot \frac{1}{x} = \frac{x}{x^2+y^2}$

d) $f(x, y) = x^3 - x^2\sin(y) - y$

$f_x = 3x^2 - 2x\sin(y). \quad f_y = -x^2\cos(y) - 1$

Higher Order Partial Derivative

- $\frac{\partial^2 f}{\partial x^2} = \frac{\partial}{\partial x}\left(\frac{\partial f}{\partial x}\right) = f_{xx}$

- $\frac{\partial^2 f}{\partial y^2} = \frac{\partial}{\partial y}\left(\frac{\partial f}{\partial y}\right) = f_{yy}$

$\cdot \frac{\partial^2 f}{\partial x \partial y} = \frac{\partial}{\partial x}\left(\frac{\partial f}{\partial y}\right) = f_{xy}$

- $\frac{\partial^2 f}{\partial y \partial x} = \frac{\partial}{\partial y}\left(\frac{\partial f}{\partial x}\right) = f_{yx}$

- If $f(x, y)$ is continuous function, $f_{xy} = f_{yx}$

1. find I & II order partial derivatives of
   a) $t = x^2 y$
   A) $f_x = 2xy$. $f_y = x^2, f_{xy} = 2x, f_{yx} = 2x, f_{xx} = 2y, f_{yy} = 0$
   b) $x^3 f(x, y) = x^3 \sin(y)$

$f_x = 3x^2 \sin(y), f_{xx} = 6x \sin(y), f_{yx} = 3x^2 \cos(y)$
$f_y = x^3 \cos(y), \quad f_{yy} = -x^3 \sin(y), \quad f_{xy} = -3x^2 \sin(y)$

Differentials

If $z = f(x, y), dz, dx, dy$ are known as differentials. in z, z, y respectively.
cex $dz = \frac{\partial z}{\partial x} dx + \frac{\partial z}{\partial y} dy$
1.) find the differentiols in f of if $f = \frac{x^3}{3} - xy^2$

$$df = \frac{df}{\partial x}\frac{\partial f}{\partial x} dx + \frac{\partial f}{\partial y} dy$$
$$df = \left(x^2 - y^2\right) dx - 2xy dy$$

Exact Differential Equation

- A Differential equation of the form $M(x, y)dx + N(x, y)dy = 0$ is sard to be exact differential equation.

such that $\frac{\partial \mu}{\partial x} = m(x, y), \& \frac{\partial \mu}{\partial y} = N(x, y)$
ie, $Mdx + Ndy = \frac{\partial \mu}{\partial x} dx + \frac{\partial \mu}{\partial y} dy = d\mu$

$$\therefore \text{ Solution is } \int d\mu \Rightarrow \mu(x, y) = c$$

Methnd to find exact or not

- If Diff. eqn. is exact then $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$

eg: $(1 - x) \cdot dx - (1 + y)dy = 0$
$M = 1 - x, \quad N = -(1 + y)$
$\frac{\partial M}{\partial y} = 0, \quad \frac{\partial N}{\partial x} = 0 \quad \Rightarrow \frac{\partial M}{\partial y} = \frac{\partial N}{\partial x} \quad \therefore$ Eqn. is exact.
Method to solve E.D.E
Solution: $\int Mdx + \int[$ Terms in N not containing $x]dy = c$
Solve $(1 - x)dg - (1 + y)dy = 0$
A) Solution: $\int(1 - x)dx + \int -(1 + y)dy = c/2 \quad$ (soy)

$$
\begin{aligned}
x-\frac{x^2}{2}-y-\frac{y^2}{2} &= c/2 \\
\Rightarrow \quad x-y &= \frac{x^2+y^2}{2}+c/2 \\
2(x-y) &= x^2+y^2+c
\end{aligned}
$$

2. $(3x^2+4xy)\,dx+(2x^2+2y)\,dy=0$

$$
\begin{aligned}
&M=3x^2+4xy, \quad \frac{\partial M}{\partial y}=4x \\
&N=2x^2+2y \quad , \quad \frac{\partial N}{\partial x}=4x \quad \frac{\partial M}{\partial y}=\frac{\partial N}{\partial x} \Rightarrow \text{ eqn. is Exact}
\end{aligned}
$$

Solution: $\int M\cdot dx+\int[$ terms in N not containing $x]dy=c$

$$
\begin{gathered}
\int\left(3x^2+4xy\right)dx+\int 2y\cdot dy=c \\
x^3+2x^2y+y^2=c
\end{gathered}
$$

3. Why condition for exactness is $\frac{\partial M}{\partial x}=\frac{\partial N}{\partial y}$?

A) for E.DE. $\exists u(x,y):\frac{\partial u}{\partial y}=N(x,y)\cdot\frac{\partial u}{\partial x}=m(x,y)$
consider $\frac{\partial^2 u}{\partial x\partial y}=\frac{\partial N}{\partial x}, \quad \frac{\partial^2 u}{\partial y\partial x}=\frac{\partial M}{\partial y}$
since. $u(x,y)$ represents a family of curve and
it is continuous, $\frac{\partial^2 u}{\partial x\partial y}=\frac{\partial^2 u}{\partial y\partial x}\Rightarrow\frac{\partial M}{\partial y}=\frac{\partial N}{\partial x}$

2. Anodian woy]:

$m=3x^2+4xy,(1) \quad N=2x^2+2y-(2)$
$\frac{\partial M}{\partial H}=4x$
$\nrightarrow\cdot m\ 0,4xy+\Psi(x)$
$=4xy+\psi(x)-15$
comparing (1) & (3) $\psi(x)=3x^2$

4. $(2x\cos(y)+3x^2y)\,dx+(x^3-x^2\sin y-y)\,dy=0$

$$
\begin{aligned}
&M=2x\cos(y)+3x^2y && N=x^3-x^2\sin(y)-y \\
&\tfrac{\partial M}{\partial y}=-2x\sin(y)+3x^2, && \tfrac{\partial N}{\partial x}=3x^2-2x\sin(y) \\
&\tfrac{\partial M}{\partial y}=\tfrac{\partial N}{\partial x}\Rightarrow \text{ eqn. is EDE}
\end{aligned}
$$

Solution: $\int(2x\cos(y)+3x^2y)\,dx+\int -ydy\pm c$

$$
x^2\cos(y)+x^3y-\frac{y^2}{2}=c
$$

Hw:

1. Solve:

a) $\left(5x^4+3x^2y^2-2xy^3\right)dx+\left(2x^3y-3x^2y^2-5y^4\right)dy=0$

b) $(2xy+y-\tan(y))dx+\left(x^2-x\tan^2(y)+\sec^2(y)+2y\right)dy=0$

2. (another uy).

$$M=3x^2+4xy, N=2x^2+2y$$

Define $f(x,y)$ f $f_x=m.f_y=N$
Then solution is given by $f(x,y)=c_1$

1. Integrate f_x wrt.ge to find $f(x,y)$:

$$f(x,y)=\int\left(3x^2+4yx\right)dx=x^3+2x^2y+\psi(y)$$

Differentiate this curty to find $\psi(y)$:

$$\partial f_y=2x^2+\frac{d\psi}{dy}$$

Substitute $f_y=N, \quad$ (by $def.$)

$$2x^2+\frac{d\psi}{dy}=2x^2+2y\Rightarrow\frac{d\psi}{dy}=2y$$

Integrate $d\psi$ sixy urty: $\psi(y)=y^2$
substitute $\psi(y)$ in $f(x,y)$:

$$f(x,y)=x^3+y^2+2x^2y$$

The Solution is $f(x,y)=c$:

$$\begin{gathered}
:\frac{x^3+y^2+2x^2y=c}{2}\\
x^4+y^2+2x^2y=x^4-x^3+c\\
\Rightarrow\left(y+x^2\right)^2=x^4-x^3+c\\
y+x^2=\pm\sqrt{x^4+x^3+c}\\
y=-x^2\pm\sqrt{x^4-x^3+c}
\end{gathered}$$

$?\frac{dy^4}{dx}+\frac{xy}{1-x^2}=x\sqrt{y}$
divide by $\sqrt{y}$.

$$y^{-1/2}\frac{dy}{dx}+\frac{xy^{1/2}}{1-x^2}=x \tag{1}$$

let $z=y^{1/2}, \quad \frac{dz}{dx}=\frac{1}{2}y^{-1/2}\frac{dy}{dx}$
$\therefore$ (1) become:

$$\frac{dz}{dx}+\underbrace{\frac{dx}{2\left(1-x^2\right)}}_{p}\cdot z=\frac{1}{2}x.$$

let $f = e^{\frac{1}{e}\int \frac{x}{1-x^2}dx} = (1-x^2)^{-1/4} \quad -\frac{1}{2}\int \frac{x}{1-x^2}dx \; t = 1-x^2 \; dt = dx\cdot(-2x)$

$$s : \mathbb{Z}\cdot F = \int Q\cdot F\cdot dx + c = -2x\cdot dx$$

$$\Psi\cdot\left(1-x^2\right)^{-1/4} = \int \frac{1}{2}x\cdot\left(1-x^2\right)^{-1/4}dx + c \quad -\frac{1}{4}\int\frac{dt}{t} \Rightarrow\Rightarrow n(t)$$

$$= \quad \frac{1}{2}\int x\cdot\left(1-x^2\right)^{-1/4}dx + c \quad \text{- (2)}$$

$\therefore$ Solution is: $y\cdot F = \int Q\cdot F\cdot dx + c$
let $t = 1-x^2, dt = -2xdx$
$\therefore$ (2) becomes:

$$y\cdot\left(1-x^2\right)^{-1/4} = -\frac{1}{4}\int t^{-1/4}dt + c$$

$$= -\frac{1}{4}x\frac{t^{3/4}}{-1/4+1} = -\frac{1}{3}\cdot t^{3/4} + c$$

$$z\cdot\left(1-x^2\right)^{-1/4} = -\frac{1}{3}\left(1-x^2\right)^{3/4} + c$$

$$z = -\frac{1}{3}\left(1-x^2\right) + c\cdot\left(1-x^2\right)^{1/4}$$

$$z = \sqrt{y}$$

$$\therefore y = \left[\sqrt[4]{c\cdot(1-x^2)} - \frac{1}{3}\left(1-x^2\right)\right]^2$$

$$\frac{dy}{dx} + x\cdot\sin(2y) = x^3\cdot\cos^2(y)$$

$$\equiv \frac{dy}{dx} + x\cdot 2\cdot\sin(y)\cos(y) = x^3\cdot\cos^2(y)$$

Divide by $\cos^2(y)$:

$$\sec^2(y)\cdot\frac{dy}{dx} + 2x\cdot\tan(y) = x^3$$

let $z = \tan(y) = \frac{dz}{dx} = \sec^2(y)\cdot\frac{dy}{dx}$.

$$\frac{dz}{dx} + 2x\cdot z = x^3$$

I.F $= e^{\sqrt{2x}} = e^{x^2}$, &multiply by it:

$$e^{x^2}\frac{dz}{dx} + 2x\cdot e^{x^2}\cdot z = x^3\cdot e^{x^2}$$

$$\Rightarrow \quad e^{x^2}\cdot z = \int x^3\cdot e^{x^2}dx^+ + c$$

$$= \frac{1}{2}e^{x^2}\left(x^2-1\right) + c$$

$$\therefore \tan(y) = \frac{1}{2}\left(x^2-1\right) + e^{-x^2}\cdot c$$

3. $\frac{dy}{dx} + y\tan(x) = y^3\cdot\sec(x)$

EDE -Hw-1

$$\underbrace{\left(5x^4+3x^2y^2-2xy^3\right)}_{M}dx+\underbrace{\left(2x^3y-3x^2y^2-5y^4\right)}_{N}dy=0$$

$$M_{xy}=6x^2y-6xy^2, N_y=6x^2y-6xy^2$$
$$M_y=N_y \quad \therefore \text{ EDE}$$

$\therefore$ So ln: $\int_{\text{cor}} mdx+\int(N \cancel{x})dxy=C$

$$=x^5-y^5+x^3y^2-x^2y^3=c$$

29/9

$$\left(3x^2+6xy^2\right)dx+\left(6x^2y+4y^3\right)dy=0$$

Solve:

a) $[\cos(x)\tan(y)+\cos(x+y)]dx+\left[\sin(x)\cdot\sec^2(y)+\cos(x+y)\right]dy=0$

A) $M=\cos(x)\tan(y)+\cos(x+y)\cdot\frac{\partial M}{\partial y}=\cos(x)\cdot\sec^2(y)-\sin(x+y)$

$$N=\sin(x)\sec^2(y)+\cos(x+y),\frac{\partial N}{\partial x}=\sec^2(y)\cdot\cos(x)-\sin(x+y)$$

$\frac{\partial M}{\partial y}=\frac{\partial r}{\partial x}\Rightarrow$ Equation is exact.

$\therefore$ Solution is:

$$\int_{y\cdot\text{ cons}}M\cdot dx+\underbrace{\int(\text{tem}\,s\,\text{in}\,N\text{ not containing }x)dy\,d}_{0}=c$$

$$\tan(y)\int\cos(x)dx+\int\cos(x+y)dx \quad =c$$
$$\tan(y)\cdot\sin(x)+\sin(x+y)=c$$

1. $(y\cos(x)+1)dx+\sin(x)dy=0$
2. $\left(\sec(x)\tan(x)\tan(y)-e^x\right)dx+\left(\sec(x)\sec^2(y)dy=0\right.$

Linear D.E with Constant Coeffis.

It is eqn of form.

$$a_0\cdot\frac{d^ny}{dx^n}+a_1\frac{d^{n-1}y}{dx^{n-1}}+\cdots+a_{n-1}\frac{dy}{dx}+a_ny=\phi(x)$$

where $a_i\in\mathbb{R}$,

If $\phi(x)=0:$ to solve this we have to change the equation to symbolic form. is $\left(a_0D^n+Da,D^{n-1}+\cdots\right)$ s
0$ ItS Auxillary equation is: $\left(a_\theta m^n+a_1m^{n-1}+\cdots\right)$ ky $=0$

From the auxillory equation we get the roots, $m_1,m_2,\cdots$ Now we procede by following rales. (which depends on nature of roots.

Roots	complimentary f_x
1 Roots are Rd equal	$(c_1 + c_2x)\, e^{m_1x}$
$m_1 = m_2$	$c_1e^{m_1x} + c_2e^{m_2x}$
$m_1 \neq m_2$	
2) $m_1 = m_2 = m_3$	$(c_1 + c_2x + c_3x^2)\, e^{m_1x}$
3) $m_1 \neq m_2 \neq m_3.$	$(c_1e^{m_1x} + c_2e^{m_2x} + c_3e_3x$
4)$m_1 = m_2 \neq m_3$	$(c_1 + c_22e^{m_1x} + c_3e^{m_3x}$
4) $\mathbb{I} : \alpha \pm i\beta$	$e^{\alpha x}\,(c_1\cos(\beta x) + c_2\sin(\beta x))$

- From the nature of roots, we get complimentary function, Hence the Solution is:

$$y = C \cdot F$$

1. Solve $\frac{d^2y}{dx} + \frac{\int}{dx} + 6y = 0$

Symbolic form: $(D^2 + 5D + 6)\, y = 0 \Rightarrow (D + 3)(D + 2) = 0$
$\therefore$ roots are: $m = -3, -2$
Real & distinct.
$\therefore$ complimentary function is : $c_1 \cdot e^{m \cdot x} + c_2 \cdot e^{m_2x}$

$$= c_1e^{-2x} + c_2e^{-3x}$$

$\therefore$ Solution is: $\quad y = c_1e^{-2x} + c_2e^{-3x}$
2 Solve $(D^3 + 1)\, y = 0$
$\rightarrow D^3 = -1 \quad \Rightarrow \quad$ roots ar: $, -1, \frac{1}{2} \pm \frac{\sqrt{2}}{2}i$
usang: $(a + b)\,(a^2 - ab + b^2)$

$$\rightarrow (D + 1)\left(D^2 - D + 1\right) = 0$$
$$\Rightarrow \quad D + 1 = 0 \Rightarrow \text{ root } = -1$$
$$D^2 - D + 1 = 0 \Rightarrow \text{ root } = \frac{1 \pm \sqrt{3}i}{2}$$

$CF: \quad e^{1/2x}\left(c_1\cos\left(\frac{\sqrt{3}}{2}x\right) + c_2\sin\left(\frac{\sqrt{3}}{2}x\right)\right) + c_3 \cdot e^{-x}$

To find particular seder integral $\frac{\phi(e)}{5}$
Case

$$I : \phi(x) = e^{ax}, \text{ put } D = a$$

e.g: $\frac{d^2y}{dx} - 13\frac{dy}{dx} + 12y = e^{-2x}$

$$\rightarrow \underbrace{\left(D^2 - 12D + 12\right) y}_{=0 \rightarrow \text{ roots}} = e^{-2x}$$
$$\therefore C \cdot F = c_1e^x + c_2e^{12x}$$

$\therefore$ Porticulor integral : $PI = \frac{e^{-2x}}{D^2 - 13D + 12} \quad , D = -2,$

$$\Rightarrow \frac{e^{-2x}}{4 + 26 + 12} = \frac{e^{-2x}}{42}$$

$\therefore$ Solution: $y = CF + PI$

$$= c_1 e^{x} + c_2 e^{12x} + \frac{e^{-2x}}{42}$$

$$6D^2 y - D_y - 2y = e^{4x} \quad , \quad 6$$

$$\therefore \text{ Auy-fx } = 6D^2 - D - 2, \text{ rooks } = \frac{+1 \pm \sqrt{1 + 4 \times 6 \times 2}}{12} = \frac{1 \pm 7}{12} \Rightarrow \frac{2}{3} - \frac{1}{2}$$

$$\therefore CF = c_1 e^{2/3x} + c_2 e^{1/2x}$$

$$PI = \frac{e^{4x}}{6D^2 - D - 2} = \frac{e^{4x}}{6 \times 16 - 4 - 2} = \frac{e^{4x}}{90}$$

$\therefore$ Solution:

$$y = CF + PF$$
$$= c_1 e^{\frac{2}{3}x} + c_2 e^{\frac{1}{2}x} + \frac{e^{4x}}{90}$$
$$y = c_1 \sqrt[3]{e^{x}}^2 + c_2 \sqrt{e^{x}} + e^{4x}/90$$

Particular Integral
case 2 : $\phi(x) = \cos(ax)$ or $\sin(ax)$, put $D^2 = a - a^2$?. Solve $(0^2 + 4)\, y = \cos(3x)$
Aux. $f_x = D^2 + 4$, roots $= \pm 2i$
$\therefore CF = e^{ox}\left(c_1 \cdot \sin(2x) + c_2 \cdot \cos(2x)\right) = c_1 \cdot \sin(2x) + c_2 \cdot \cos(22)$
$PI = \frac{\cos(3x)}{D^2+4} = \frac{\cos(3x)}{-9+4} = \frac{\cos(3x)}{-5}$
$\therefore y = CF + PI$
$= c_1 \sin(2x) + c_2 \cdot \cos(2x) - \frac{\cos(3x)}{5}$
II? $(D^2 - 3D + 2)\, y = \sin(3x)$

&\Rightarrow e^x\cdot(x\sin(x)+2\cos(x))\\
&\therefore\ \text{soln}\quad y=\left(c_1+c_2x-x\sin(x)-2\cos(x)\right)e^x
\end{aligned}
$$

Cauchy's LDE
General form:

$$
a_0x^n\cdot\frac{d^ny}{dx^n}+a_1x^{n-1}\frac{d^{n-1}y}{dx^{n-1}}+\cdots+a_xx^{dy}dx+y=\phi(x)
$$

is reduced to LDE with Const. coett by substituting

$$
\begin{aligned}
&x=e^t,\text{ or }t=\ln(x)\quad\frac{d}{dt}=D,\because x^2\cdot\frac{d^2y}{dx^2}\Rightarrow D(D-1)y\\
&x\frac{dy}{dx}=Dy\quad:\quad x^3\frac{d^3y}{dx^3}\to D(D-1)(D-2)y
\end{aligned}
$$

Solve:
1). $x^2\cdot\frac{d^2y}{dx^2}-x\frac{dy}{dx}+y=\ln(x)$
This if Cauchy's LDG $\therefore$ put $x=e^t,\Rightarrow\sin(x)=t$
Redue to LDE with const-eoeth.

$$
\begin{aligned}
(1)\quad \to & D(D-1)y - Dy + y = t \\
& \left(D^2 - 2D + 1\right) y = t \\
& \therefore CF = (c_1 + c_2 t)\, e^t
\end{aligned}
$$

$$
\begin{aligned}
P_I &= \frac{t}{(D-1)^2} \to \\
&= \frac{t}{D^2 - 2D + 1} = \left(1 + \left(D^2 - 2D\right)\right)^{-2} = \\
&= \left(1 - D^2 + 2D\right) t \\
&= t + 2 \\
&= \ln(x) + 2
\end{aligned}
$$

$\therefore$ solution: $y = (c_1 + c_2 \ln(x))\, e^{\ln(x)} + \ln(x) + 2$

$$
\begin{aligned}
&= \oint_1 + r_2 \ln(x) \Big] \, x + \ln(x) + 2 \\
&= c_1 x + \ln(x)\,(1 + x c_2) + 2
\end{aligned}
$$

2. $x^2 \cdot y'' - 4xy' + 6y = x^2$

put $x = e^t, t = \ln(x)$

$$
\begin{aligned}
& D(D-1)y - 4Dy + 6y = e^{2t} \\
& \left(D^2 - 5D + 6\right) y = e^{2t} \\
& D = \frac{e^{2t}}{D^2 - 5D + 6}, \quad CF = c_1 e^{+3x} + c_2 e^{-12x} \\
& \therefore PI_1 = 2 \\
& \Rightarrow \frac{e^{2t}}{4 - 10 + 6} = \\
& \frac{+5 \pm \sqrt{25 - 25}}{2} = \frac{+5 \pm 1}{2} \\
& = +2, -3 \\
& \frac{e^{2t}}{(D-3)(D-2)} \Rightarrow \frac{1}{D-2} \cdot \frac{te^{2t}}{D-3} = -te^{2t}
\end{aligned}
$$

$\therefore$ Solution: $y = c_1 e^{3t} + c_2 e^{2t} + te^{2t}$

$$
= c_1 e^{\ln(x)^2} + c_2 e^{2 \cdot \ln(x)} - \ln(x) e^{2 \ln(x)}
$$

$$
\begin{aligned}
&= c_1 x^3 + c_2 x^2 - \ln(x) x^2 \\
y &= c_1 x^3 + x^2 \left(c_2 - \ln(x)\right)
\end{aligned}
$$

HT

3. $x^2 y'' - 2xy' - 4y = x^4$.
4. $x^2 y'' + 4xy' + 2y = x^2 + x^{-2}$

In 10

H.

Simultaneous LDE

It contains two or more dependent variables (soy x, y.. and one inclependent variable (say t)

1. $\frac{dx}{dt} = 7x - y, \quad \frac{dx}{dt} - \frac{dy}{dt} = 5(x-y)$
   A)

$$
\begin{aligned}
& \frac{dx}{dt} - 2x = y = 0 \rightarrow (D-7)x + y = 0 && (1) \\
& \frac{dx}{dt} - \frac{dy}{5x} - \frac{dy}{dx} + 5y = 0 \rightsquigarrow (D-5)x + -(D-5)y = 0 && (2) \\
& (D-5) \times 0: \\
& (D-7)(D-5)x + (D-5)y = 0 \\
& +[(D-5)\dot{x} - (D-5)y = 0] \\
& \underbrace{\left(D^2 - 11D + 30\right)}_{\text{aux ff}} x = 0 \\
& = \\
& \therefore \text{ costs of aux ff } z \\
& 5, 6 \\
& \therefore C \cdot F_{12} x = C, e^{5t} + C_2 e^{6t}
\end{aligned}
$$

$$D = \frac{d}{db}$$

$\therefore$ (1) becomv.

$$
\begin{aligned}
& (D-7)\left(c_1 e^{st} + c_2 e^{st}\right) + y = 0 \\
& \Rightarrow = 5c_1 e^{st} + 6c_2 e^{6t} - 7c_1 e^{st} - 7c_2 e^{-st} = -y \\
& \Rightarrow y = 2c_1 e^{st} + c_2 e^{6t}
\end{aligned}
$$

$$\& \quad x = c_1 e^{5t} + c_2 e^{6t}$$

$2\frac{dx}{dt} + 2x - 3y = t \quad , \quad \frac{dy}{dt} - 3x + 2y = e^{2t}$

A)

$$
\begin{aligned}
& (D+2)x - 3y = t \\
& (D+2) \text{ y } - 3x = e^{2t} && (2) \\
& \text{ (1) } \times 3 : 8 \\
& 3x(D+2) - 9y = 3t && (3) \\
& +\left(-3x(D+2) + (D+2)^2 y = (D+2)e^{2t}\right) && (9)
\end{aligned}
$$

(3) + (4)

$$
\begin{aligned}
&y\left((D+2)^2-4\right)=3t+4e^{2t}\\
&y\left(D^2+4D-5\right)=3t+4e^{2t}\\
&=y(D+5)(D-1)\cdot\\
&\therefore \quad \text{roots } =-5,+1\\
&\therefore CF_{\text{an }y}c_1e^{-5t}+C_2e^{+t}
\end{aligned}
$$

$$
\begin{aligned}
PI_{y_1}=&\frac{3t}{(D^2+4D-5)}\\
&=-\frac{3}{5}\times\left(1+\left(\frac{D^2}{-5}-\frac{4}{5}D\right)\right)^{-1}t\\
&=-\frac{3}{5}\times\left(1-\frac{D^2}{-5}+\frac{4}{5}Dx^2+\cdots\right)t\\
&=-\frac{3}{5}\left(t+0+\frac{4}{5}\right)\\
PI_{y_1}=&\frac{4e^{2t}}{(D+5)(D-1)}\\
&\Rightarrow\frac{4}{7}t-\frac{12}{25}\\
&\Rightarrow y=CF_y+PI_{y_1}+PI_{y_2}\\
&\therefore y=C_1e^{-5t}+C_2e^t-\frac{3}{5}t+\frac{4}{7}e^{2t}-\frac{12}{25}
\end{aligned}
$$

Substitute in (2):

$$
\begin{aligned}
&(D+2)y-e^{2t}=3x\Rightarrow x=\frac{1}{3}\left[(D+2)y-\frac{t}{2}e^{2t}\right]\\
&x=\frac{1}{3}\left(-5c_1e^{-5t}+c_2e^t-\frac{3}{5}+\frac{8}{7}e^{2t}\right.\\
&\left.+2c_1e^{-5t}+2c_2e^t-\frac{6}{5}t+\frac{8}{7}e^{2t}-\frac{24}{25}-e^{2t}\right)\\
&=\frac{1}{3}\left(-3c_1e^{-5t}+3c_2e^t+\frac{9}{7}e^{2t}-\frac{6}{5}t-\frac{39}{25}\right)\\
&\qquad x=-c_1e^{-5t}+c_2e^t+\frac{3}{7}e^{2t}-\frac{2}{5}t-\frac{13}{25}
\end{aligned}
$$

3.

$$
\begin{aligned}
\frac{dx}{dt}+2y&=-\sin(t),\\
\frac{dy}{dt}&=2x+\cos(t)
\end{aligned}
$$

A) $\frac{dx}{dt}+2y=-\sin(t)$-1

$$
\begin{aligned}
&\frac{dx}{dt}+2y=-\sin(t)-(D)(D-2)x+(D+2)y=\cos(t)-\sin(t)\\
&\frac{dy}{dt}-2x=\cos(t)\quad \text{(D)}
\end{aligned}
$$

(1) $\times 2$,

$$2x \cdot 0 + 4y = -2\sin(t)$$

(2) $\times 0$.

$$D^2 \cdot y - 2x \cdot D = D \cdot \cos(t) - (4)$$

(3) + (4):

$$\begin{aligned}
&D^2 \cdot y + 4y = -3\sin(t) \\
&\frac{d^2y}{dt} + 4y = -3\sin(t) \\
&\therefore \quad ye^{4t} = \int e^{4t}x - 3\sin(t)dt = -3\int \sin(t)e^{4t} \cdot dt
\end{aligned}$$

$$\begin{aligned}
I &= -3\int \sin(t)e^{4t}dt \quad I_2 = \cos(t)4e^{44} + \underbrace{4\int \sin(t)\ldots} \\
&= -3(\sin(t) \times 4e^{4t} - 4\underbrace{\cos(t) \cdot e^{4t}}_{I}) \quad = 40\cos(t)e^{4t} + 4I \\
&= -8\sin(t)e^{4t} + 32\cos(t)e^{4t} + 32I \\
\therefore &= \frac{e^{4t}}{4^2+1}(4\sin(t) - \cos(4t)
\end{aligned}$$

$$\begin{aligned}
&\therefore \quad = \frac{e^{4t}}{4^2+1}(4\sin(t) - \cos(\theta t) \\
&\text{or } \left(p^2+4\right)y = -3\sin(t) \\
&\therefore y = (c_1\cos(2t) + c_2\sin(2t)) \\
&PI = \frac{-3\sin(t)}{D^2+4}, \quad D^2 = -1 \\
&\Rightarrow -\frac{3}{3}\sin(t) = -\sin(t) \\
&\therefore y = c_1\cos(2t) + c_2\sin(2t) - \sin(t)
\end{aligned}$$

Substitute this in (2):

$$\begin{aligned}
&\Rightarrow x = -e^{2t}\left(\cos^5\left(-c_1 + c_2\right)\right. \\
&\Rightarrow x = -2e^{2t}\left(c_1+c_2\right)\cos(2t) + \left(c_2 - c_1\right)\sin(2E)) - \tfrac{1}{16} - \cos(t) \\
2 &= -\frac{1}{2}\left(\cos(t) - 2c_1\sin(2t) + 2c_2\cos(2t) - \sin(t)\right)
\end{aligned}$$

Hew 1. $\frac{dy}{dt} + 2y + x = \sin(t) \quad \frac{dx}{dt} - 4y - 2x = \cos(t)$ H)

$$\begin{aligned}
&Dy + 2y + x = \sin(t) \\
&Dx - 4y - 2x = \cos(t)
\end{aligned}$$

$\mathcal{C} \times \bar{\partial} D$:

$$\begin{aligned}
&-D^2y + 2Dy - Dx = -\cos(t) \\
&\oplus -4y + Dx - 42x = \sin(t) \\
&-\left(+D^2 + 2D + 4\right)y - 2x = \sin(t) - \cos(t)
\end{aligned}$$

(20) 2

$$\therefore + \frac{2Dy + 4y + 2x = 2\sin(t)}{4D^2 + 3)}$$

$$- D^2 y = 3\sin(t) - \cos(t)$$

$$\therefore y = \int (\cos(t) - 3\sin(t)) dt dt$$

$$= \int (\sin(t) + 3\cos(t)) dt$$

$$y = 3\sin(t)\cos(t) \quad y = 2\sin(t) + ct + 2$$

$\therefore$ from (0: $8\sin(t) + B3\cos(t) + 266\sin(t) - 2\cos(t) + x = \sin(t)$ $\therefore x = -6\sin(t) - \cos(t) \quad x = -3\sin(t) - 2\cos(\theta$

$$-2ct + 2c_2 + c$$
